

Mutant *ilvH* gene and Method for producing L-valine

Technical Field

5 This invention relates to a method for producing
L-valine by fermentation, particularly, a DNA coding for
acetohydroxy acid synthase isozyme III which is free from
feedback inhibition by L-valine, a microorganism which
harbors the DNA, and a method for producing L-valine using
10 the bacterium.

Background Art

15 In the past, L-valine has been produced by a method
of fermentation primarily using a microorganism belonging
to the genus *Brevibacterium*, *Corynebacterium* or *Serratia* or
a mutant thereof which produces L-valine or L-leucine (Amino
acid fermentation, JAPAN SCIENTIFIC SOCIETY'S PRESS,
pp.397-422, 1986). Although the conventional methods have
20 considerably enhanced the productivity of these amino acids,
the development of a more efficient, cost-effective
technique is required in order to meet increasing demand for
L-valine and L-leucine in the future.

As bacteria other than above-mentioned bacteria
25 used for production of L-valine, it is exemplified by L-

valine producer belonging to the genus *Escherichia* which requires lipoic acid for growth and/or which is deficient in H⁺-ATPase activity, and a bacterium belonging to the genus *Escherichia* which has preceding characteristics and which 5 is introduced an *ilvGMEDA* operon expressing *ilvG*, *ilvM*, *ilvE* and *ilvD* genes and not expressing threonine deaminase (WO96/06926).

The final step of L-valine biosynthesis is carried out by a group of *ilvGMEDA* operon-encoded enzymes. The 10 *ilvGMEDA* operon includes each of *ilvG*, *ilvM*, *ilvE*, *ilvD* and *ilvA* genes, which encodes a large subunit and a small subunit of isozyme II of acetohydroxy-acid synthase, transaminase, dihydroxy-acid dehydratase and threonine deaminase, respectively. Of these enzymes, acetohydroxy-acid synthase, 15 transaminase and dihydroxy-acid dehydratase catalyze the synthetic pathways from pyruvic acid to L-valine and from 2-ketobutyric acid to L-isoleucine, and threonine deaminase catalyzes the deamination from L-threonine to 2-ketobutyric acid, which is a rate-limiting step of L-isoleucine 20 biosynthesis. Incidentally, the expression of *ilvGMEDA* operon suffers control (attenuation) by L-valine and/or L-isoleucine and/or L-leucine.

As acetohydroxy acid synthase concerning L-valine biosynthesis, isozyme III (hereinafter, also referred to as 25 AHAS III) is known, apart from isozyme II (hereinafter, also referred to as AHAS II). AHAS III is coded by *ilvIH* operon

which consists of *ilvI* coding for a large subunit (catalytic subunit) and *ilvH* coding for a small subunit (control subunit). AHAS III suffers feedback inhibition by L-valine.

Incidentally, it has been reported that the mutant
5 *ilvH* gene cloned from the mutant *Escherichia coli* resistant to L-valine had an amino acid substitution of ¹⁴Gly with Asp (Vyazmensky, M. et al., Biochemistry, 35, 10339-10346 (1996)). Further, *ilvH612* has been known as the AHAS III mutation (De Felice et al., J. Bacteriol., 120, 1058-
10 1067(1974)). The *ilvH* gene in the *ilvIH* operon of *Escherichia coli* MI262 (Guardiola et al., J. Bacteriol., 120, 536-538 (1974); De Felice et al., J. Bacteriol., 120, 1068-
15 1077(1974)) contains the *ilvH612* double mutation by which ²⁹Asn is substituted with Lys and ⁹²Gln is substituted with a termination codon(TAG), respectively.

As described above, a DNA coding for AHAS II has been utilized for breeding of L-valine producer, however, for AHAS III no case has been reported.

20

Disclosure of the Invention

The object of the present invention, in view of the aforementioned points, is to provide a DNA coding for AHAS III which is free from a feedback inhibition by L-valine,
25 a microorganism which harbors the DNA, and a method for

producing L-valine using the bacterium.

As a result of diligent investigation in order to achieve the object described above, the present inventors found that L-valine productivity is increased when a DNA coding for valine resistant AHAS III isolated from an L-valine resistant mutant is introduced into *Escherichia coli*.
5 Thus the present invention has been completed.

That is, aspects of the present invention are as follows:

10 (1) A DNA coding for a small subunit of acetohydroxy acid synthase isozyme III originating from *Escherichia coli* which has a mutation to replace an amino acid residue corresponding to serine residue at the amino acid number 17 with another amino acid residue in SEQ ID NO: 2, or both of

15 a mutation to replace an amino acid residue corresponding to serine residue at the amino acid number 17 and a mutation to replace an amino acid residue corresponding to glycine residue at the amino acid number 14 with another amino acid residue in SEQ ID NO: 2;

20 (2) The DNA of (1), wherein the mutation of the amino acid residue corresponding to serine residue at the amino acid number 17 is replacement of the serine residue with phenylalanine residue and the mutation of the amino acid residue corresponding to glycine residue at the amino acid number 14 is replacement of the glycine residue with
25 aspartic acid residue;

(3) A DNA coding for acetohydroxy acid synthase isozyme III originating from *Escherichia coli* which is free from an inhibition by L-valine and has an activity to catalyze two reactions to generate α -acetolactate from pyruvate and α -aceto- α -hydroxybutyrate from α -ketobutyrate and pyruvate;

(4) The DNA of (3), wherein the DNA codes for a large subunit and a small subunit of acetohydroxy acid synthase isozyme III, the small subunit having a mutation to replace 10 an amino acid residue corresponding to serine residue at the amino acid number 17 with another amino acid residue, or a mutation to replace an amino acid residue corresponding to asparagine residue at the amino acid number 29 with another amino acid residue, or a mutation to delete a C-terminal 15 region from the amino acid number 91 downwards, in SEQ ID NO: 2, or a combination of two or more mutations selected from the group consisting of aforementioned mutations and a mutation to replace an amino acid residue corresponding to glycine residue at the amino acid number 14 with another 20 amino acid residue in SEQ ID NO: 2.

(5) The DNA of (4), wherein the mutation of the amino acid residue corresponding to serine residue at the amino acid number 17 is replacement of the serine residue with phenylalanine residue, the mutation of the amino acid residue corresponding to aspartic acid residue at the amino 25 acid number 29 is replacement of the aspartic acid residue

with lysine residue or tyrosine residue, and the mutation of the amino acid residue corresponding to glycine residue at the amino acid number 14 is replacement of the glycine residue with aspartic acid residue;

5 (6) A bacterium which harbors the DNA according to claims 1 or 3 on chromosomal DNA or plasmid in the bacterium and has an ability to produce L-valine;

(7) The bacterium of (6), wherein expression of the DNA is enhanced;

10 (8) The bacterium of (7), wherein the expression is enhanced by locating the DNA under the control of a potent promoter or amplifying a copy number of the DNA;

15 (9) A method for producing L-valine comprising the steps of cultivating the bacterium according to claim 6 in a culture medium, producing and accumulating L-valine in the culture medium, and collecting L-valine from the culture medium.

The present invention will be explained in detail below.

20 The first DNA of the present invention is a DNA encoding a small subunit of AHAS III which exhibits acetohydroxy synthase activity without suffering a feedback inhibition by L-valine along with a large subunit.

25 Acetohydroxy synthase activity herein refers to an activity to catalyze two reactions to generate α -acetolactate from pyruvate, and α -aceto- α -hydroxybutyrate from α -

ketobutyrate and pyruvate. AHAS III small subunit of *Escherichia coli* has an amino acid sequence depicted in SEQ ID NO: 2 in Sequence Listing.

Aforementioned mutation is selected from a mutation
5 to replace an amino acid residue corresponding to serine
residue at the amino acid number 17 with another amino acid
residue in SEQ ID NO: 2, or both of a mutation to replace
an amino acid residue corresponding to serine residue at the
amino acid number 17 and a mutation to replace an amino acid
10 residue corresponding to glycine residue at the amino acid
number 14 with another amino acid residue in SEQ ID NO: 2.
As the mutation, for the amino acid residue corresponding
to serine residue at the amino acid number 17 it is
preferably exemplified by replacement of the serine residue
15 with phenylalanine residue, and for the amino acid residue
corresponding to glycine residue at the amino acid number
14 it is preferably exemplified by replacement of the
glycine residue with aspartic acid residue.

The second DNA of the present invention is a DNA
20 coding for AHAS III which is free from inhibition by
L-valine and has an activity to catalyze two reactions to
generate α -acetolactate from pyruvate and α -aceto- α -
hydroxybutyrate from α -ketobutyrate and pyruvate. The DNA
encode the large subunit and the small subunit of AHAS III,
25 simultaneously.

The small subunit has a mutation to replace an amino

acid residue corresponding to serine residue at the amino acid number 17 with another amino acid residue, or a mutation to replace an amino acid residue corresponding to asparagine residue at the amino acid number 29 with another amino acid residue, or a mutation to delete a C-terminal region from the amino acid number 91 downwards, in SEQ ID NO: 2, or a combination of two or more mutations selected from the group consisting of aforementioned mutations and a mutation to replace an amino acid residue corresponding to glycine residue at the amino acid number 14 with another amino acid residue in SEQ ID NO: 2. The small subunits of AHAS III which have these mutations also hereafter referred to as mutant small subunit of AHAS III. As the mutation, for the amino acid residue corresponding to serine residue at the amino acid number 17 it is preferably exemplified by replacement of the serine residue with phenylalanine residue, and for the amino acid residue corresponding to aspartic acid residue at the amino acid number 29 it is exemplified by replacement of the aspartic acid residue with lysine or tyrosine residue, and for the amino acid residue corresponding to glycine residue at the amino acid number 14 it is preferably exemplified by replacement of the glycine residue with aspartic acid residue.

The DNA of the present invention was obtained from L-valine resistant mutant of *Escherichia coli*, however, it may be obtained by inducing above mutation or mutations into a DNA encoding wild type AHAS III by site-directed

mutagenesis. AHAS III is coded by *ilvIH* operon. The *ilvIH* operon can be obtained by, for example, amplifying the DNA fragment which is from the promoter region to 3' end of *ilvH* gene by PCR using primers having sequences depicted in SEQ 5 ID NOS: 3 and 4 from genomic DNA of *Escherichia coli* as a template. The nucleotide sequence of *ilvIH* operon has been known (Genbank/EMBL/DDBJ accession X55034). The nucleotide sequence of coding region of *ilvH* is illustrated in SEQ ID NO: 1.

10 The mutant small subunit of AHAS III coded by the DNA of the present invention may have an amino acid sequence which includes substitution, deletion, insertion, addition, or inversion of one or several amino acids as well as aforementioned mutation, provided that the mutant small 15 subunit exhibits acetohydroxy acid synthase activity without suffering a feedback inhibition by L-valine along with the large subunit.

A DNA, which codes for the substantially same protein as the mutant small subunit as described above, is 20 obtained, for example, by modifying the nucleotide sequence, for example, by means of the site-directed mutagenesis method so that one or more amino acid residues at a specified site involve substitution, deletion, insertion, addition, or inversion. DNA modified as described above may be 25 obtained by the conventionally known mutation treatment. The mutation treatment includes a method for treating DNA

coding for the small subunit *in vitro*, for example, with hydroxylamine, and a method for treating a bacterium belonging to the genus *Escherichia* harboring the DNA coding for the small subunit with ultraviolet irradiation or a 5 mutating agent such as N-methyl-N'-nitro-N-nitrosoguanidine (NTG) and nitrous acid usually used for the mutation treatment.

The DNA, which codes for substantially the same protein as mutant small subunit of AHAS III, is obtained by 10 expressing DNA having mutation as described above in multicity in an appropriate cell, investigating the resistance to L-valine, and selecting the DNA which increase the resistance. Also, it is generally known that an amino acid sequence of a protein and a nucleotide sequence coding 15 for it may be slightly different between strains, mutants or variants, and therefore the DNA, which codes for substantially the same protein, can be obtained from L-valine resistant species, strains, mutants and variants belonging to the genus *Escherichia*.

20 Specifically, the DNA, which codes for substantially the same protein as the mutant small subunit, can be obtained by isolating a DNA which hybridizes with DNA having, for example, a nucleotide sequence shown in SEQ ID NO: 1 in Sequence Listing under stringent conditions, and 25 which codes for a protein having the acetohydroxy acid synthase activity, from a bacterium belonging to the genus

Escherichia which is subjected to mutation treatment, or a spontaneous mutant or a variant of a bacterium belonging to the genus *Escherichia*. The term "stringent conditions" referred to herein is a condition under which so-called specific hybrid is formed, and non-specific hybrid is not formed. It is difficult to clearly express this condition by using any numerical value. However, for example, the stringent conditions include a condition under which DNAs having high homology, for example, DNAs having homology of not less than 70% with each other are hybridized, and DNAs having homology lower than the above with each other are not hybridized.

The bacterium of the present invention harbors the first DNA or the second DNA of the present invention and has an activity to produce L-valine. The bacterium is not particularly limited so long as it has a biosynthetic pathway of L-valine which acetohydroxy acid synthase concerns with. It is exemplified by a bacterium belonging to the genus *Escherichia*, coryneform bacteria and the genus *Serratia*, preferably by the genus *Escherichia*. A bacterium belonging to the genus *Escherichia* is concretely exemplified by *Escherichia coli*.

Examples of a method for introducing the DNA of the present invention into a bacterium include, for example, a method in which a bacterium is transformed with a plasmid containing the DNA of the present invention, and a method

in which the DNA of the present invention is integrated into chromosomal DNA of a bacterium by homologous recombination, or the like.

It is preferable that expression of the DNA of the present invention is enhanced. The enhancement of expression is achieved by locating the DNA of the present invention under the control of a potent promoter or amplifying a copy number of the DNA. For example, *lac* promoter, *trp* promoter, *trc* promoter, *tac* promoter, P_R promoter, P_L promoter of lambda phage, *tet* promoter, *amyE* promoter and *spac* promoter are known as potent promoters. Also, it is possible to increase the copy number of the DNA of the present invention by maintaining the DNA on a multi-copy vector or introducing multiple copies of the DNA into the chromosomal DNA. The multi-copy vector is exemplified by pBR322, pTWV228, pMW119 and pUC19 or the like.

To introduce the vector containing the DNA of the present invention to a host bacterium, any known transformation methods can be employed. For instance, employable are a method of treating recipient cells with calcium chloride so as to increase the permeability of DNA, which has been reported for *Escherichia coli* K-12 [see Mandel, M. and Higa, A., *J. Mol. Biol.*, 53, 159 (1970)]; and a method of preparing competent cells from cells which are at the growth phase followed by introducing the DNA

thereinto, which has been reported for *Bacillus subtilis* [see Duncan, C.H., Wilson, G.A. and Young, F.E., *Gene*, 1, 153 (1977)]. In addition to these, also employable is a method of making DNA-recipient cells into the protoplast or spheroplast which can easily take up recombinant DNAs followed by introducing the recombinant DNA into the cells, which is known to be applicable to *Bacillus subtilis*, actinomycetes and yeasts [see Chang, S. and Choen, S.N., *Molec. Gen. Genet.*, 168, 111 (1979); Bibb, M.J., Ward, J.M. and Hopwood, O.A., *Nature*, 274, 398 (1978); Hinnen, A., Hicks, J.B. and Fink, G.R., *Proc. Natl. Sci., USA*, 75, 1929 (1978)], or a method transformation used in embodiments of the present invention is the electric pulse method (refer to Japanese Patent Publication Laid-Open No. 2-207791).

Applicable method to introduce the DNA of the present invention into bacterial chromosomal DNA includes a method utilizing linearized DNA and that utilizing a plasmid containing a temperature-sensitive replication origin. Alternatively, the DNA of the present invention may be introduced into a bacterium from a bacterium harboring the DNA of the present invention on its chromosomal DNA by transduction.

In order to introduce multiple copies of the DNA of the present invention into the chromosomal DNA of a bacterium, the homologous recombination is carried out using a sequence whose multiple copies exist in the

chromosomal DNA as targets. As sequences whose multiple copies exist in the chromosomal DNA, repetitive DNA, inverted repeats exist at the ends of a transposable element can be used. Also, as disclosed in Japanese Patent 5 Publication Laid-Open No. 2-109985, it is possible to incorporate the DNA of the present invention into transposon, and allow it to be transferred to introduce multiple copies of the DNA into the chromosomal DNA.

The bacterium to which the DNA of the present invention is introduced may be a bacterium being acquired L-valine productivity by introduction of the DNA of the present invention as well as a bacterium inherently having L-valine productivity.

Examples of bacteria having L-valine productivity includes, for example, *Escherichia coli* VL1970 (US Patent 5 658 766). Additionally, bacteria described in WO96/06926 such as L-valine producer belonging to the genus *Escherichia* which requires lipoic acid for growth and/or which is deficient in H⁺-ATPase activity, or a bacterium belonging to the genus *Escherichia* which is introduced an *ilvGMEDA* operon expressing at least *ilvG*, *ilvM*, *ilvE* and *ilvD* genes are preferably used. Since the expression of *ilvGMEDA* operon suffers control (attenuation) by L-valine and/or L-isoleucine and/or L-leucine, it is preferable that the region which is essential for attenuation is deleted or mutated to desensitize the repression of expression by

produced L-valine. Another approach suggests the introduction of the mutations (ileS or valS) affecting aminoacyl-tRNA synthases having decreased affinity (increased the Km) for the corresponding amino acids.

- 5 Further, the operon which does not express active threonine deaminase is used preferably.

Escherichia coli VL1970 containing ileS17 mutation in which attenuation is desensitized as described above has been deposited in Russian National Collection of Industrial Microorganisms (VKPM) Depositary, GNIigenetika, (1, Dorozhny Proezd., 1, 113545, Moscow, Russia) under the accession number of VKPM B-4411.

The methods to perform, for example, hybridization, PCR, preparation of plasmid DNA, digestion and ligation of DNA, and transformation are described by Sambrook, J., Fritzsche, E. F., Maniatis, T. in *Molecular Cloning*, Cold Spring Harbor Laboratory Press, 1.21 (1989).

The production of L-valine can be performed by culturing the bacterium having L-valine productivity in a medium, to allow L-valine to be produced and accumulated in the medium, and collecting L-valine from the medium.

In the present invention, the cultivation, the collection and purification of L-valine from the medium and the like may be performed in a manner similar to the conventional fermentation method wherein an amino acid is produced using a microorganism. A medium used for culture

may be either a synthetic medium or a natural medium, so long as the medium includes a carbon source and a nitrogen source and minerals and, if necessary, appropriate amounts of nutrients which the microorganism requires for growth. The
5 carbon source may include various carbohydrates such as glucose and sucrose, and various organic acids. Depending on the mode of assimilation of the used microorganism, alcohol including ethanol and glycerol may be used. As the nitrogen source, various ammonium salts such as ammonia and ammonium sulfate, other nitrogen compounds such as amines,
10 a natural nitrogen source such as peptone, soybean-hydrolysate and digested fermentative microorganism are used. As minerals, potassium monophosphate, magnesium sulfate, sodium chloride, ferrous sulfate, manganese sulfate, calcium carbonate, and the like are used.
15

The cultivation is performed preferably under aerobic conditions such as a shake culture, and an aeration and stirring culture, at a temperature of 20 to 40 °C , preferably 30 to 38 °C . The pH of the culture is usually
20 between 5 and 9, preferably between 6.5 and 7.2. The pH of the culture can be adjusted with ammonia, calcium carbonate, various acids, various bases, and buffers. Usually, a 1 to 3-day cultivation leads to the accumulation of the target L-valine in the liquid medium.

25 After cultivation, solids such as cells can be removed from the liquid medium by centrifugation and

membrane filtration, and then the target L-valine can be collected and purified by ion-exchange, concentration and crystallization methods.

5

Brief Explanation of Drawings

Fig. 1 shows PCR primer for obtaining the mutant ilvH gene containing only one mutation: ¹⁴Gly to Asp; and

10 Fig. 2 shows PCR primer for obtaining the mutant ilvH gene containing only one mutation: ¹⁷Ser to Phe.

Best Mode for Carrying Out the Invention

15 The invention is described with reference to the following example:

<1> L-valine resistant strains of *E. coli* W3350

An L-valine resistant mutant was selected on minimal medium containing 0.1 mg/ml of L-valine from *E. coli* 20 wild type strain W3350. Thus obtained mutant W3350 Val_{0.1}^R is resistant to L-valine concentrations not higher than 1 mg/ml.

Then leucine operon (*leuABCD*) in which transposon Tn10 was inserted (*leu::Tn10*) was introduced into W3350 _{0.1}^R

by P1 transduction. From the W3350 Val_{0.1}^R leu::Tn10 transductant, a double mutant strain was induced, which grew on minimal medium containing 20mg/ml of L-valine and 0.05 mg/ml of L-leucine.

5

<2> Breeding of L-valine producing strain VL1991

10 *E. coli* VL1970 (VKPM B-4411, US Patent 5 658 766) was introduced a gene participating resistance to high concentraion of threonine(>40 mg/ml) or homoserine (>5. mg/ml) which was isolated from a strain B3996 having a mutation (*rhtA23*) participating the resistance (US Patent 5 705 371). Thus the strain VL1971 was obtained.

15 Then the sucrose utilization genes from *E. coli* VL478 was introduced into VL1971 by transduction using P1 phage to obtain VL1972. And then from VL1972 a spontaneous mutant VL1991 was induced, which grew faster than the parent strain.

<3> Introduction of L-valine resistance to VL1991

20 The mutations which was contained in the above-mentioned double mutant was introduced into VL1991 by P1 transduction. A spontaneous mutant which was Leu⁺ was selected from the transductants. The mutant was designated as VL1997. Then a *ilvD* gene to which Tn10 had been inserted (ilvD::Tn10) was introduced into VL1997 by P1 transduction

to obtain VL1997 *ilvD*::Tn10. VL1997 *ilvD*::Tn10 was then transduced with *ilvGMEDA* operon from *E. coli* strain B. From the thus obtained VL1998 a spontaneous mutant VL1999 was selected, which grew faster than the parent strain.

5

<4> L-valine producing strain VL1999/pVL715

The strain VL1999 was transformed with the plasmid pVL715 to obtain the recombinant valine producing strain VL1999/pVL715. The plasmid pVL715 was constructed as follows. The *Bam*HI-*Xma*III DNA fragment containing the *ilv* genes (*ilvGMEDAYC*) was cut out from the plasmid pVR12 (Gavrilova et al., *Biotechnology* (in Russian), 4, No.5, 600-608 (1988)) which contains the genes, and subsequently inserted to pAYC32, a RSF1010 derivative (Chistoserdov and Tsygankov, *Plasmid*, 1986, v.16, pp.161-167) substituting *Bam*HI-*Xma*III DNA fragment of pAYC32, to give the plasmid pVS712. Then the plasmid pVL715 was derived from pVS712, which suppresses the *valS91* mutation affecting valyl-tRNA synthetase (US Patent 5 658 766) as follows. pVS712 was introduced into the *valS91* mutant. The resulted strain, *ValS91/pVS712*, retained valine auxotrophy as the recipient strain. Then the "revertants" capable of growth in minimal medium containing no valine were selected. In some of them this property was caused by a mutation in the *ilvGMEDAYC* genes contained in the pVS712 plasmid. From one of the "revertant" the plasmid pVL715 was isolated. In *E. coli*

strains containing pVL715 at least AHAS activity was enhanced as compared to those containing pVS712.

5 <5> Identification of the mutations conferring L-valine
resistance

From W3350 Val_{0.1}^R and VL1997 *ilvIH* genes were cloned and sequenced. The cloning of the *ilvIH* genes were performed by amplifying the DNA fragments which were from the promoter region to 3' end of *ilvH* gene by PCR using primers having sequences depicted in SEQ ID NOS: 3 and 4. PCR was carried out by the condition: 94 °C 60 sec, 48 °C 30 sec, 72 °C 90 sec, 30 cycles. The amplified *ilvIH* genes were treated with Klenow fragment and cloned into *HincII* site of pUC19 vector to give pILVIH1 and pILVIH1,2. In the same manner, a wild type *ilvIH* operon from the strain W3350 was cloned in pUC19 to obtain pILVIH.

Comparative sequence analysis revealed that the mutant IlvIH operon of W3350 Val_{0.1}^R contains substitution: "C" to "T" at the nucleotide number 50 and that of VL1997 contains two substitutions: "C" to "T" at the nucleotide number 50 and "G" to "A" at the nucleotide number 41 in SEQ ID NO: 1. These mutations caused amino acid substitutions of ¹⁷Ser to Phe and ¹⁴Gly to Asp. The mutation of ¹⁷Ser to Phe and that of ¹⁴Gly to Asp may be referred to as *ilvH1* mutation and *ilvH2* mutation, respectively. The *ilvH* genes containing one or both of these mutations were designated as *ilvH1*,

ilvH2 and *ilvH1,2*, respectively.

<6> Separation of *ilvH1* mutation and *ilvH2* mutation from
ilvH1,2 mutant gene

5 In order to elucidate the effect of each mutation
of *ilvH1,2* these mutation was separated by site-directed
mutagenesis using PCR.

10 To obtain the mutant *ilvH* gene containing only one
mutation: ¹⁴Gly to Asp, the fact that this mutation creates
a unique *Mlu*I site was utilized (Fig.1). Thus, two primers
15 having sequences depicted in SEQ ID NOS: 5 and 6 were
synthesized.

15 Using above primers, a plasmid pILVIH1,2 in which
ilvH1,2 gene was cloned was amplified by PCR. Thus, the
linearized DNA fragment of about 5 kb which was flanked by
*Mlu*I sites was produced. This PCR fragment was cut with *Mlu*I
and subsequently ligated to give the circular plasmid,
pILVIH2, containing only the target mutation. This was also
proved by sequence analysis.

20 To obtain a mutant *ilvH* gene containing only one
mutation: ¹⁷Ser to Phe, two primers having sequences
depicted in SEQ ID NOS: 7 and 8 were designed (Fig. 2).

25 Using these primers, a plasmid pILVIH containing
wild type *ilvIH* operon was amplified. The PCR fragment
produced was flanked by *Stu*I sites created by substitution

of ATA (coding for Ile) for the adequate codon ATT. The fragment was cut with *Stu*I and ligated to give the circular plasmid pILVIH1' containing the newly introduced mutation point ¹⁷Ser to Phe. This was substantiated by sequencing 5 the *ilvH1* gene of the plasmid.

<7> Identification of other mutations conferring L-valine resistance

From two L-valine resistant mutants derived from *E. coli* W3350 which were obtained in the same manner as described above, *ilvH* genes were cloned and sequenced. As a result, it was revealed that substitution of "T" for "A" at the nucleotide number 85 in SEQ ID NO: 1 was caused in one mutant and substitution of "A" for "C" at the nucleotide number 87 in SEQ ID NO: 1 was caused in another mutant. By these mutations ²⁹Asn was replaced with Tyr or Lys, respectively. The mutation of ²⁹Asn to Tyr and that of ²⁹Asn to Lys may be referred to as *ilvH3* and *ilvH4*, respectively. From these mutants the *ilvIH* operons were cloned in pUC19 20 to obtain pILVIH3 and pILVIH4, respectively.

In the same manner, *ilvIH* operon was cloned in pUC19 from *E. coli* MI262 (*IlvI*⁻, *IlvB*⁻, *IlvG*⁻), obtained from *E. coli* Genetic Stock Center, which has a known mutation of AHAS III, *ilvH612* (Guardiolae et al., *J. Bacteriol.*, 120, 536-538 25 (1974); De Felice et al., *J. Bacteriol.*, 120, 1068-1077(1974))) to obtain pILVIH262. The *ilvH* gene in the

operon in pILVIH262 has mutations(ilvH612): "C" to "A" at the nucleotide number 87 in SEQ ID NO: 1 and "C" to "T" at the nucleotide number 274 in SEQ ID NO: 1. By these mutations ²⁹Asn is replaced with Lys and ⁹²Gln is substituted with a 5 termination codon (TAG), respectively. Incidentally, the *ilvI* gene in the *ilvIH* operon of MI262 has a mutation (ilvI614) by which the expression product of the *ilvI* gene does not show an enzyme activity. The *Bam*HI fragment of 10 pILVIH262 containing mutated *ilvI* gene was replaced with *Bam*HI fragment containing the wild type *ilvI* gene of pILVIH to obtain pILVIH612.

<8> Introduction of *ilvH1* gene to wild type strain of *E. coli*

The mutant *ilvH1* gene was introduced into the 15 chromosome of *E. coli* strain W3350 using the previously described method (Parker and Marinus, 1988, Gene, v.73, pp.531-535). Thus the strain W3350 *ilvH1* was obtained. It proved that this strain was resistant up to 1 mg/ml of 20 L-valine, that is, it showed the same level of resistance as the strain W3350 Val_{0.1}^R.

Thus, by both sequence analysis of the *ilvH1* gene and *ilvH1* mutation which was separated from *ilvH2* mutation of the *ilvH1,2* mutant by site-directed mutagenesis, it was confirmed the mutation point: ¹⁷Ser to Phe, which confer upon 25 cells low level resistance to L-valine.

<9> Effect of the various *ilvH* mutations on AHASIII
resistance to L-valine inhibition

The mutation *IlvH1* (¹⁷Ser to Phe), *ilvH2* (¹⁴Gly to Asp), *ilvH3* (²⁹Asn to Lys), *ilvH4* (²⁹Asn to Tyr) and *ilvH612* (²⁹Asn to Lys and ⁹²Gln to a termination codon, TAG),
5 conferred enzyme AHASIII resistance to L-valine inhibition
as follows. That is, *E. coli* strain MI262 deficient of AHAS
activity, after the introduction of the plasmids having
various *ilvIH* genes showed the enzyme activity with
10 different level of resistant to L-valine (Table 1). It can
also be seen that AHAS from the strains containing pILVIH2
or pILVIH612 plasmids exhibits the highest level of
resistance to L-valine.

15 Table 1. Effect of the various *ilvH* mutations on AHAS
resistance to L-valine inhibition

Plasmid	AHAS inhibition by valine, %	
	1 mM	10mM
pILVIH	70	>99.9
pILVIH1	50	70
pILVIH2	0	10
pILVIH3	10	20
pILVIH4	8	12
pILVIH612	0	0

<10> Effect of the various *ilvH* mutations on L-valine production

The effect of various *ilvH* mutations on L-valine production was examined. The mutations were introduced into 5 the chromosome of the strains VL1970 and VL1999/pVL715. Incidentally, the parent strain (W3350) of the strains VL1970 and VL1999 does not express an active acetohydroxy acid syntase II (AHAS II), since the parent strain has a frame-shift mutation in the *ilvG* gene. On the other hand 10 the strains VL1970 and VL1999 express an active AHAS II.

After the introduction of various *ilvH* mutations into the strain VL1970 the new strains VL1970 *ilvH1*, VL1970 *ilvH1,2*, VL1970 *ilvH3*, VL1970 *ilvH4*, VL1970 *ilvH612* were obtained. Besides, after the introduction of various *ilvH* mutations into the strain VL1999/pVL715 the new strains 15 VL1999 *ilvH1,2 /pVL715*, VL1999 *ilvH3 /pVL715*, VL1999 *ilvH612 /pVL715* were obtained. These strains and the respective parental strains were each cultivated at 37°C for 18 hours in a nutrient broth, and 3 ml of a fermentation 20 medium having the following composition in a 20 x 200 mm test tube, was inoculated with 0.3 ml of the obtained culture, and cultivated at 37°C for 72 hours with a rotary shaker (250 r.p.m.). After the cultivation, an accumulated amount of valine in the medium and an absorbance at 560 nm of the medium 25 were determined by known methods.

The results are presented in Table 2 and Table 3.

In these tables, *ilvH⁺* indicates the wild type *ilvH* gene.

Fermentation medium composition (g/L):

	Glucose	80
5	(NH ₄) ₂ SO ₄	22
	K ₂ HPO ₄	2
	NaCl	0.8
	MgSO ₄ *7H ₂ O	0.8
	FeSO ₄ *7H ₂ O	0.02
10	MnSO ₄ *5H ₂ O	0.02
	Thiamine hydrochloride	0.2
	Yeast Extract (Sigma)	1.0
	CaCO ₃	30

(CaCO₃ was separately sterilized)

15

Table 2. Effect of the different *ilvH* mutations

on L-valine production by the strains VL1970

Strain	OD ₅₆₀	L-Valine (g/L)
VL1970	19.4	10.2
VL1970 <i>ilvH1</i>	20.1	11.4
VL1970 <i>ilvH1,2</i>	19.5	12.6
VL1970 <i>ilvH3</i>	18.2	12.62
VL1970 <i>ilvH4</i>	17.2	11.7
VL1970 <i>ilvH612</i>	18.4	12.8

Table 3. L-valine production by the strain VL1999/pVL715
containing different mutations in *ilvH* gene

Strain	OD ₅₆₀	L-Valine(g/L)
VL1999 <i>ilvH</i> ⁺ /pVL715	17.6	18.7
VL1999 <i>ilvH</i> _{1,2} /pVL715	18.9	23.4
VL1999 <i>ilvH</i> ₃ /pVL715	19.4	20.6
VL1999 <i>ilvH</i> ₆₁₂ /pVL715	17.7	20.2

5 It can be seen from the Table 2 and Table 3 that the introduction of the *ilvH* mutations described above improved valine productivity of the respective valine producing strains. Also, the combination of *ilvH*₁ and *ilvH*₂ mutations may give the best result.

10 The pUC19 derivatives which have *ilvIH* operons containing various mutant *ilvH* genes were introduced into the strain W3350. Incidentally, the strain W3350 does not express an active AHAS II, since the strain has a frame-shift mutation in the *ilvG* gene. It can be seen from the 15 Table 4 that the obtained transformants produced L-valine, and that the strain containing the plasmid pILVIH_{1,2} was the most productive.

Table 4. L-valine production by the strain W3350 harboring plasmids with different mutant *ilvH* genes

Strain	OD ₅₆₀	L-Valine (g/L)
W3350	21.4	0
W3350/pILVIH1	13.8	2.3
W3350/pILVIH1,2	10.5	8.2
W3350/pILVIH3	11.7	5.9
W3350/pILVIH4	16.4	5.5

Previously the present inventors observed that in the course of L-valine fermentation the activity of AHAS in the producer's cells (mainly presented by AHAS II) was gradually decreasing. It was shown that half-life of AHAS III at 45 °C was 144 min., and that of AHAS II was 44 min.

(Alexander-Caudle *et al.*, *J. Bacteriol.* 172, 3060-3065 (1990)). It may be suggested that this increased thermostability of AHAS III reflects the general increased stability of the enzyme. Therefore it is thought that L-valine-resistant AHAS III has positive effect on L-valine production because of its increased stability as compared to AHAS II.
